Abstract

Background and aims: Recently, silver nanoparticles (AgNPs) have received much attention for their possible usage in various fields. This study examined the effect of AgNPs on the histopathological changes in the prostate of rats.

Methods: In this study, 40 male adult Wistar rats were divided into five equal groups (n=8 in each group). AgNPs were given orally to the four experimental groups at doses of 30, 125, 300, and 700 mg/kg for 28 consecutive days. The control group received deionized water. After performing hematoxylin and eosin (H&E) staining and Masson's trichrome staining, the histological changes in the prostate of rats were evaluated.

Results: Histological evaluation showed that the acinar epithelial height and alveolar folds decreased, but vacuoles in the epithelial cells and accumulation of blood vessel increased in the groups treated with AgNPs at doses of 30 and 125 mg/kg. The collagen content also increased significantly in these groups (30 mg/kg: $P=0.03$ and 125 mg/kg: $P=0.002$). Furthermore, the groups treated with AgNPs at doses of 300 and 700 mg/kg showed relative normalization acini and epithelial lining and the amount of their content.

Conclusion: According to the results of current study, oral administration of AgNPs for 28 days had effects on prostate, indicating the toxicity of AgNPs.

Introduction

Nanotechnology is a multidisciplinary scientific field of applications manufactured at the molecular level. Due to its increasing progress, nanotechnology can cause revolutionary advances across such sciences as medicine, communications, genomics, and robotics (1). The extensive use of nanoparticles (NPs) is based on their distinctive chemical and physical properties, such as large surface area, small size, and high reactivity potential (2).

Silver nanoparticles (AgNPs) are one of the most common types of NPs that are widely used in different products including medicine, food industry, textiles, electronics, and pharmaceutical preparations (3,4).

AgNPs can enter the body through different ways, such as injection, inhalation, oral, and dermal route. Since AgNPs are being used in different food products, including water and liquid beverages, nutritional supplements, toothpastes, and drug carriers, the digestive tract is the notable absorption route for them (4,5).

In vitro and in vivo investigations have shown that

exposure to AgNPs can lead to inflammatory reaction (6), DNA damage (7), and histological changes in the kidneys, lungs, liver, endocrine, and the male reproductive system (8). There are several studies on the toxic effects of AgNPs on the testis and sperms (9-11). The potential adverse effect of administering AgNPs orally on the histology of prostate, which is one of the male accessory sex glands, has not been addressed well. Thus, this study aimed to investigate the potential toxic effect of oral subchronic exposure to AgNPs on histology of the prostate in rats.

Material and Methods

AgNP solution

AgNPs in powder form (CAS No. 7440-22-4) was dispersed in deionized water and prepared concentrations of 30, 125, 300, and 700 mg/kg using vigorous vortexing sonication for 5 minutes.

The size distribution of the NPs was analyzed using dynamic light-scattering (DLS; Malvern, Nano ZS ZEN-3600, UK).

Administration of AgNPs

In this study, 40 adult male Wistar rats with weights of 180-200 g were used. The rats were kept in the animal house under a natural light/dark cycle with standard conditions of $21\pm 2^{\circ}\text{C}$ and $50\pm 5\%$ humidity. The rats were divided into five equal groups (four intervention vs. one control). The four experimental groups were administered orally with 30, 125, 300, and 700 mg/kg AgNPs for 28 days and the rats in the control group received equal volumes of deionized water. At the end of the treatment period, body weight was measured, and the animals were sacrificed. For histological study, the anterior lobes of prostates were removed and fixed in 10% neutral buffered formalin.

Histological Study

Formalin-fixed prostatic tissues were processed routinely, blocked in paraffin after gradient dehydration, sectioned, deparaffinized, and rehydrated. The 5 μm sections prepared using the rotary microtome and stained with hematoxylin and eosin (H&E). Masson's trichrome staining was also used to assess the collagen density. The images for histological examination were obtained through light microscope with video camera (Motic 2003). The ImageJ software was used for the acquisition of the collagen density.

Statistical Analysis

SPSS software version 16.00 (SPSS Inc., USA) was used for statistical analysis. Data were expressed as means $\pm$ standard error (SE). The results were statistically analyzed using one-way ANOVA with subsequent Tukey's test. To compare the selected pairs of groups, probability level of <0.05 was considered as statistically significant.

Results

Characterization of Silver Nanoparticles

The AgNPs suspension was analyzed under dynamic light scattering (DLS) for size. The results showed the hydrodynamic diameter in range of 200-300 nm (Figure 1).

Body and Organ Weight

Table 1 shows the body weight gain and prostate weight.

There were no significant ($P>0.05$) dose-related changes in the body weight gains and prostate weight in the treated rats compared to the control ones.

Histological study

H&E-stained sections

The histological changes of the prostate gland in the rats administered with AgNPs were analyzed. The results showed that the acinar epithelial height and alveolar folds decreased and the acini lined by flattened epithelium. The vacuoles in the epithelial cells, thickness of muscle fibers, the ratio of parenchyma to stroma, and the blood vessel accumulation were increased in treated rats. Prostate of rats treated with 30 and 125 mg/kg AgNPs revealed more prominent histological changes compared to the rats treated with 300 and 700 mg/kg AgNPs (Table 2 and Figure 2).

Masson's trichrome staining

Masson's trichrome quantified the intensity of collagen deposition. The collagen intensity increased in the groups treated with AgNPs at the doses of 30 mg/kg ($P=0.03$) and 125 mg/kg ($P=0.002$) compared to the control. The collagen content was almost similar in normal renal tissues in groups treated with AgNPs at the doses of 300 and 700 mg/kg (Figure 3).

Discussion

AgNPs are used in many food and medical products. Many studies suggest that AgNPs could potentially be toxic (12-16). Despite lots of benefits of AgNPs, a dose-dependent

Table 1. Body weight gain and prostate weight of rats after oral treatment with AgNPs for 28 days

Group	Body weight gain	Prostate weight (g)
Control	72.72 $\pm$ 19.50	0.54 $\pm$ 0.11
30 mg/kg	61.02 $\pm$ 8.045	0.32 $\pm$ 0.14
125 mg/kg	76.63 $\pm$ 18.57	0.45 $\pm$ 0.15
300 mg/kg	64.52 $\pm$ 7.98	0.65 $\pm$ 0.15
700 mg/kg	67.05 $\pm$ 2.29	0.58 $\pm$ 0.09

* No significant difference was seen ($P=0.1$)
Data are expressed as mean $\pm$ SD.

Table 2. Effect of treatment with AgNPs (30, 125, 300, and 700 mg/kg) for 28 days on prostate qualified histological criteria

	Control	30 mg/kg	125 mg/kg	300 mg/kg	700 mg/kg
Folded secretory alveolar	++	-	-	-	+
Vacuoles in the epithelial cells	-	+	+	-	-
Thickness of muscle fibers	-	+++	+++	++	+
Level of parenchyma to stroma	-	++	++	+	-
Blood vessel accumulation	+	++	+++	+++	++
Epithelial heights	+	-	-	+	+
Secretory content	+	++	+++	+	+

Note. The (-) absent, (+) mild, (++) moderate, and (+++) severe schemes were used to score the histological alterations.

Figure 1. Dynamic light scattering (DLS) results of the characterization of silver nanoparticles.

Figure 2. Effect of silver nanoparticle on histology of prostate tissue in rats (H&E staining $\times 10$). (A) Control group has normal structure, the acini lined with folded cuboid epithelium, and empty lumen. (B and C) The groups treated with 30 and 125 mg/kg AgNPs show acini with flattened lining epithelium (the acini with cystic atrophy appearance) and decreased folding and increased secretion in acini. (D and E) The groups treated with 300 and 700 mg/kg AgNPs show tissue compact acini; the epithelial lining, folding, and contents were relatively the same as control group.

study to monitor impact of AgNPs exposure on animal and human health seems to be necessary. The results of studying biodistribution of AgNPs in rats have shown that they are dose- and size-dependent. The accumulation of AgNPs in different cells, such as reproductive cells, causes changes in sperm parameters (17-20). An *in vivo* toxicity experiment was performed on Sprague–Dawley rats, orally treated for 28 days with nano-silver by Kim et al at doses of 30, 300, and 1000 mg/kg per day (17). The current study extended these concentrations with some modification to assess whether AgNPs treated orally can have adverse impacts at prostate of rats.

Figure 3. The collagen deposition in prostate of rats treated with 30, 125, 300, and 700 mg/kg concentrations of AgNPs. Data are shown in mean $\pm$ SD. Significant differences shown as: **a**: compared to control group ($P=0.002$), **b**: to 125 mg/kg group ($P=0.01$), **c**: to 300 mg/kg group ($P=0.007$), and **d**: to 700 mg/kg group ($P=0.001$).

There were no significant dose-related changes in the body weight gains and weight of prostate of the rats. These results agree with those of Kim et al (18) that did not show any significant changes in body and prostate weight relative to various concentrations of AgNPs during the 28-day experiment by oral and inhalation exposures.

In current study, the histological examinations showed that dose-dependent AgNPs induced lesions in prostate gland. There were increased vacuoles in epithelial cells, the acini lined by flattened epithelium with cystic changes and increased secretory material in their lumina, and widened stroma at doses 30 and 125 mg/kg AgNPs, while the prostatic alveoli at 300 and 700 mg/kg showed prostatic tissue with acini and epithelial lining and the contents were relatively the same as control group. The results of this study showed that these changes were more frequent in groups treated with 30 and 125 mg/kg AgNPs concentrations, indicating toxicity induction by these doses.

The activity of the prostate was dependent on stimulation by the testicular hormones. It was shown that the prostatic epithelium was very sensitive to androgen deprivation (21). A decrease was detected in testosterone in rats' treatment with AgNPs (22).

Results of this study revealed the marked deposition of collagen within the stroma in the 30 and 125 mg/kg treated groups. Interstitial tissue fibrosis involves excessive accumulation of collagen fibrils and is a feature of many diseases that progress to chronic prostatic changes (23). NPs can cause induced stress oxidative, which increase glycation of collagen fibers (24,25).

In confirmation of the effect of toxic substances on vacuolar degeneration and acini changes, the results of the effect of non-carcinogenic dose of cadmium (26), carbimazole (27), and different kinds (28-30) of NPs showed almost the same results.

Regarding vascular alterations, it seems this inflammatory response results from the oxidative stress caused by AgNPs and leads to vascular congestion (31).

Because of the strong oxidation potential, the excessive amounts of reactive oxygen species are induced by NPs. This could result in the destruction of organelle structures and different biomolecules, that finally lead to necrosis and apoptosis (32,33).

The increased activity of the testicular marker enzyme, γ -Glutamate trans peptidase (γ -GT), prostate specific antigen (PAP) (34), increased serum prostate-specific antigen level (PSA) and acyl carrier protein (ACP) might indicate injury of the prostate gland (35). The elevated PSA level probably indicates the disruption of the cellular basement membrane within the prostate gland acini and ducts leading to leakage of PSA into the prostatic parenchyma, and eventually increasing its serum concentration (36).

In addition to morphological changes, some marker changes have also been found in different nanoparticles threatening in prostate (29,37). Recent studies showed an increase in PSA, PAP concentrations, γ -GT, and ACP activity after ZnONPs (37) and nano-sized titanium dioxide treatment (29).

In the present study, it seems that the more severe histological changes in rats administered by 30 and 125 mg/kg concentrations and slight damage in 300 and 700 mg/kg/d concentrations are due to translocation of AgNPs into prostate. In addition, it might be due to the agglomeration of AgNPs used in this study (~250 nm hydrodynamic diameter agglomerates). After oral administration, the small intestine is the first site for absorption of NPs. The large agglomeration size of AgNPs in high concentration may also have prevented their intestinal absorption and so resulted in an insufficient amount being available to the prostate. Similar changes were observed by Kim et al (17) and Kulthong et al (38).

Conclusion

The present study demonstrated that AgNPs induced histological changes in prostate and fibrosis by repeated oral administration.

Conflict of Interests

There is no conflict of interests.

Ethical Approval

All procedures were approved by the Ethics Committee of Hamadan University of Medical Sciences, Iran (HUMS, IR.UMSHA. REC.1396.597).

Authors' Contribution

ZA designed the study, analyzed the data, and revised the paper. FS carried out data collection, wrote the manuscript draft. MS contributed to study design participation in analysis. MH carried out data collection.

Funding/Support

This study was supported by the Vice-chancellor for Research and Technology, Hamadan University of Medical Sciences, Iran (grant no.: 9610056181).
